**Introduction**

*Dryopteris austro-indica* Fraser-Jenk. belonging to the family Dryopteridaceae, was described by Fraser-Jenkins in 1989 on the basis of collections by R. H. Beddome (1864). This species qualifies to endangered category with limited distribution in south India (Fraser Jenkins, 2008). As per earlier reports (Fraser-Jenkins, 1989 & 2012; Ebihara et al., 2012), the plant grows in the Shevaroys Hills, Gudliar Peak and Nilgiri of Western Ghats. After Fraser-Jenk’s study, several works (Manickam, 1986; Nair et al., 1992; Nayar & Geervarghese, 1993; Theuerkauf, 1993; Leena & Madhusoodanan, 1998; Manickam & Irudayaraj, 1992) had been carried out in south India, but this species could never be collected again anywhere from south India.

While working in the ferns of Wayanad district, the first author collected an interesting specimen of *Dryopteris* from the montane forests of Kurichiyarmala and Chembra Peak (Chembramala) in Wayanad district of Kerala (Figure 1). After critical study of the specimens with help of relevant literature, and consultation with experts, it was identified as *Dryopteris austro-indica* Fraser-Jenk.–an endemic and threatened species narrowly distributed in south India. The species was hitherto unknown to fern flora of Kerala. This constitutes the first authentic record of this species from North Kerala and the same is reported here as a new addition to the fern flora of Kerala. Full citation, description, phenology, distribution, and specimens examined along with colour photographs provided to facilitate further collection, identification and conservation. The voucher specimens deposited in the herbarium of M. S. Swaminathan Research Foundation, Kalpetta, Wayanad; Calicut University Herbarium, Malappuram (CALI).

**Abstract:** *Dryopteris austro-indica* Fraser-Jenk., an interesting south Indian endemic fern species of restricted occurrence belongs to the family Dryopteridaceae. It is a threatened species narrowly distributed in south India and hitherto unknown to fern flora of Kerala. This fern is attractive for its magnificent fronds and well suited for growing in gardens as pot plants. A detailed taxonomic account of the species along with necessary photographs has been provided to facilitate easy identification of the species.

**Key Words:** *Dryopteris austro-indica*, Kurichiyarmala, Chembra Peak, Wayanad.
**Taxonomic Treatments**

Terrestrial. Rhizome erect or semi erect, covered with scales. Fronds seasonal, 5-7 per plant, up right, tufted, vegetative and fertile frond similar; stipe green, 7-15cm long, densely scaly at the base, sparsely scaly towards apex; scales ovate, glossy, pale, 6-8 x 2.5-3mm long, apex acuminate; rachis green, sparsely scaly; scales smaller than that of stipe; lamina lanceolate or ovate-lanceolate, 12-25cm long, up to 10 cm broad, simply pinnate or bipinnatifid, apex acute, young lamina light green, mature lamina dark green; pinnae lanceolate, up to 12 pairs, 3.5-7cm long, apex obtuse, coriaceous, pinna lobed, lobes up to 9 pairs, alternate, pinna-lobes joined at their bases by a narrow wing of tissue, except at the bases of the lower and middle pinnae where they become separated into pinnules, apex obtuse, margins slightly serrate towards apex, curved towards lower surface. Veins free, forked, up to 5 pairs, distinct below. Sori large, in pairs, or frequently more, close to costa, crowded, near the bases of the lobes; indusia completely enclosing the sorus, thick, white, reniform, with the dark colour of the sporangia showing through as grey, becoming brown, inflected at the edges and surrounding the sporangia even when ripe, persistent. Spores regular, dark chestnut-brown, very large (Figure 2).

**Spore:** April – October.

**Distribution:** Endemic to South India. Tamil Nadu (Nilgiris, Mallee Mand, Shevaroy Hills, Gudalir Peak); Kerala (Wayanad District: Chembra Peak (1868m), Kurichiayarmala (1657m)).

**Ecology:** It grows on the moist and shady places in beside boulders, rock crevices of grasslands above 1600 m. It also grows in forest margins of high altitude, usually not exposed to direct sunlight (Figure 3). Deciduous, seasonal pattern pronounced with new growth restricted to the rainy season, dormant during the dry months. The associated fern taxa are *Athyrium solenopteris*, *A. falcatum*, *A. anisopterum*. During summer, grassland may burn and it would cause the destruction of the plant. Spores also get destructed by such burning, resulting in to no germination of them but the underground rhizome withstand forest fire up to some extent and sprouts again during rain. This fern attractive for its shape of fronds and it is well suited for growing in gardens as pot plants. It was observed that the population is severely fragmented and area of occupancy is estimated to be less than 3 km², while the population size estimated from the localities (Chembra peak and Kurichiyarmala to number fewer than 30 mature individuals.

Specimen examined Kerala: Wayanad district, Chembra peak 05-10-2011, Mini, V. 149; 20-09-2012, Mini, V. 334; Kurichiarmala 22-08-2011, Mini, V. 125; 20-08-2012, Mini, V. 301; (M. S. Swaminathan Research Foundation Herbarium, Kalpetta, Wayanad).

Acknowledgement
We are thankful to Mr. C. R. Fraser-Jenkins for his help in identification of this species. The authors are grateful to Divisional Forest Officers, other forest officials of Wayanad Forest Division, and Mr. Satheesh K. T. for their help during the study. Also, we acknowledge the support and suggestions given by Dr. Sujana, K. A, Scientist C, Central Botanical Laboratory, Botanical Survey of India, Howrah.
